Just curious - as OS4.1FE (on my A3000) still with update1 seems to be using "old" binaries (dated 2009 and thereabouts, according to version info), is it perhaps best to update it with Roadshow, even though it is 68k? Is the TCP stack in OS4 at all maintained at this point?

Let's say that I would not recommend it, except perhaps as a research project 😊

The network interface drivers could end up calling 68k code from within interrupt processing. Overall network performance is likely to suffer, and I do not actually know if the 68k emulator is designed to be invoked in interrupt mode.

It is being maintained, it's just that the the update release cycles of the 68k and the PPC versions, respectively, of Roadshow do not overlap.

I am (sort of) free to produce 68k updates whenever I manage to find the time (which includes any additional time to fix embarrassing mistakes I made when building the update archives).

OS4 updates, by comparison, happen even less often because they need to include much more material, which requires even more time for integration & compatibility testing.

Unfortunately, the most recent OS4 update was released before I began that long overdue bug-squashing effort which would not have been possible without you.
