I've purchased "Crossfire II" some time ago, installed it but it doesn't work.

I have A1200, 68040, 32 MB Fast RAM, OS 3.1, AGA. I don't have graphics card.

During install I chose option "68030, AGA" and "medium install".
I didn't install chunkyppc.

It seems that game "thinks" that I have a gfx card. In the prefs program, below "Show intro" option, there are options "Graphics system: Amiga OS full screen, ChunkyPPC full screen, ChunkyPPC Workbench window".
(there is a picture of prefs window in game manual but without those AmigaOS/ChunkyPPC options).

When I try to load "Cfil" it tells me that can't open cybergraphics.library and Amiga crashes.

How to solve this problem?

Thomas

The readme of the demo version begins like this:

Quote:

Welcome to CrossfireII Demo. Please start the Prefs program first, change the options to whatever suits your taste and save the config. The game won't start otherwise.

Did you do this?

Yes, I did it.

BTW I have full version, not a demo.

But I haven't.

If you have demo of Crossfire II and it works on AGA Amiga with 68k, maybe you can send me a file created by prefs program?

I'll try it. Until now I only checked the documentation.

It's not necessary because I found out what was wrong.

I installed the game again but this time chose 'yes' when installer asked about installing 'chunkyppc.library'.

Game needs it even on 68k Amigas.

Game works now.

Hi, Thomas, Developer here. You're right, the ChunkyPPC lib is required on 68k, too. It's maybe an unluckily chosen name, but it's useful.
